

Vita Health: Key Gaps and Recommended Solutions

1. Unclear role of AI

Medication reminders and adherence tracking do not require AI.

Solution: Use AI for symptom guidance, personalised explanations, patient communication and identifying patterns. Keep critical clinical decisions under predefined safety rules and human supervision.

2. Safety of symptom guidance

AI should not independently determine whether a patient has a serious medical condition.

Solution: Introduce a separate clinical safety layer that detects high-risk symptoms and immediately triggers escalation.

3. Emergency response

“Seek emergency care” is too general.

Solution: Provide clear emergency actions, approved healthcare facilities, emergency contacts and caregiver/clinic alerts where appropriate.

4. Laboratory interpretation

Reference ranges differ across laboratories and patient groups.

Solution: Use the reference range provided on the patient’s laboratory report. Where information is unclear, Vita should recommend professional review rather than generate an interpretation.

5. Medication setup

Manual entry of prescriptions can create errors and unnecessary friction.

Solution: Allow the clinic to create or verify the patient’s medication plan, which Vita then converts into reminders and adherence tracking.

6. Caregiver functionality

Missed-dose notifications alone provide limited value.

Solution: Allow caregivers to receive relevant adherence alerts, view permitted information and support patients based on consent.

7. Clinic dashboard

The dashboard should not simply display patient records.

Solution: Prioritise patients requiring attention based on missed medication, abnormal results, unresolved symptoms and other risk indicators.

8. Adherence motivation

Medication streaks can make healthcare unnecessarily gamified.

Solution: Use adherence percentages and progress trends with supportive reminders.

9. Human escalation

Patients need a clear pathway from AI support to professional care.

Solution: Include a **Request Clinical Review** function that sends relevant patient information to the healthcare team.

10. Connectivity

Reliable internet access cannot be assumed.

Solution: Support offline medication reminders and adherence logging, with automatic synchronisation when connectivity returns. USSD/SMS can be considered in later phases.

11. Localisation

Language support should not be limited to direct translation.

Solution: Support local expressions and healthcare terminology through linguistic and clinical validation.

12. Stronger product positioning

This positioning doesn't make Vita stand out:

AI healthcare assistant

This can work or could be refined

Vita Health is a continuity of care platform that extends clinical support beyond the hospital, helping patients follow their care plans while giving healthcare teams visibility into problems that require intervention.

The core system should be:

Care plan → Patient support → Monitoring → Risk detection → Clinical escalation → Intervention
